A^1-Homotopy Theory

Vladimir Voevodsky

Abstract. **A**^{1}-homotopy theory is the homotopy theory for algebraic varieties and schemes which uses the affine line as a replacement for the unit interval. In the paper I present in detail the basic constructions of the theory following the sequence familiar from standard texbooks on algebraic topology. At the end I define motivic cohomology and algebraic cobordisms and describe algebraic K-theory in terms of this theory.

Contents

1   Introduction

In my talk I will outline the foundations of the **A**^{1}-homotopy theory. This theory is based on the idea that one can define homotopies in the algebro-geometrical context using the affine line **A**^{1} instead of the unit interval. My exposition will follow the sequence familiar from the standard textbooks on topological homotopy theory which roughly looks as follows.

Let $\mathcal{C}$ be a category which we want to study by means of homotopy theory. Usually $\mathcal{C}$ itself is not "good enough" and first one has to choose a convenient category of "spaces" Spc which contains $\mathcal{C}$ and has good categorical properties (in particular has internal Hom-objects and all small limits and colimits). In topology $\mathcal{C}$ may be the category of CW-complexes and Spc the category of compactly generated spaces ([8, §6.1]). Then one defines the class of weak equivalences on Spc. The localization of the category of spaces with respect to this class is then the (unstable) homotopy category H. To make the localization procedure effective one usually chooses in addition classes of cofibrations and fibrations such as to get

a closed model structure in the sense of Quillen (see [8, Def. 3.2.3] for the modern formulation of Quillen's axioms).

Next one considers suspension functors. Stabilizing with respect to these functors in the naive way one obtains a new category SW called the Spanier-Whitehead category. If the suspensions satisfy some natural conditions this new category is additive and triangulated. As a result it is more accessible to study than the original unstable category. One of the necessary conditions for this to work is that the category H should be pointed i.e. its initial and final object should coincide. Thus one always applies the stabilization construction to the homotopy category of pointed spaces.

The Spanier-Whitehead categories lack an important property - they do not have infinite coproducts (= infinite direct sums). This is a result of the naive procedure used to invert the suspension functors. To obtain a category where suspensions are inverted and which still has infinite direct sums one uses the idea of spectra. This approach produces another triangulated category which is called the stable homotopy category SH. The reason infinite direct sums are so important lies in the fact that once we have them we can apply to SH the representability theory of in [16], [17] and [18].

Thus the standard sequence of constructions in homotopy theory leads to a sequence of categories and functors of the form

$$\mathcal{C} \to Spc \to H \to SW \to SH$$

In what follows I will construct such a sequence starting with the category Sm/S of smooth schemes over a Noetherian base scheme S. A reader who is more comfortable with the language of algebraic varieties may always assume that $S = Spec(k)$ for a field k in which case $\mathcal{C}$ is the category of smooth algebraic varieties over k. At the end I will define three cohomology theories on $Spc(S)$ for any S - algebraic K-theory, motivic cohomology and algebraic cobordism. In each case one defines the theory by giving an explicit description on the spectrum which represents it. Algebraic K-theory defined this way coincides on Sm/S with homotopy algebraic K-theory of Chuck Weibel [27], motivic cohomology coincide for smooth varieties over a field of characteristic zero with higher Chow groups of S. Bloch [2] and algebraic cobordism is a new theory originally introduced in [26].

Modulo the general nonsense of the abstract homotopy theory *all* the statements of this paper except for Theorem 6.2 have simple proofs. The hard part of the work which was needed to develop the theory presented here consisted in choosing among many different plausible variants of the main definitions. I believe that in its present form the $\mathbf{A}^1$-homotopy theory gives a solid foundation for the study of cohomology theories on the category of Noetherian schemes.

Individual constructions which remind of $\mathbf{A}^1$-homotopy theory go back to the work of Karoubi-Villamayor on K-theory and more recently to the work of Rick Jardine [9],[10] and Chuck Weibel [27]. For me the starting point is [21] where the first nontrivial theorem showing that this theory works was proven. The first definition of the unstable $\mathbf{A}^1$-homotopy category equivalent to the one presented here was given by Fabien Morel. $\mathbf{A}^1$-homotopy theory for varieties over a field of characteristic zero was the main tool in the proof of the Milnor conjecture given

in [26]. The current work on the Bloch-Kato conjecture which is a generalization of Milnor conjecture to odd primes uses even more of it.

This text was written during my stay at FIM which is a part of ETH in Zurich. I am very glad to be able to use this opportunity to say that this was a very nice place to work. My special thanks go to Ruth Ebel for her help with all kinds of everyday problems.

2 SPACES

The main problem which prevents one from applying the constructions of abstract homotopy theory directly to the category Sm/S of smooth schemes over a base S is nonexistence of colimits. In classical algebraic geometry this is known as nonexistence of "contractions". One can solve this problem for particular types of contractions by extending the category to include nonsmooth varieties, algebraic spaces etc. For our purposes it is important to have *all* colimits which is not possible in any of these extended categories.

There is a standard way to formally add colimits of all small diagrams to a category $\mathcal{C}$. Consider the category of contravariant functors from $\mathcal{C}$ to the category of sets. Following Grothendieck one calls such functors *presheaves* on $\mathcal{C}$. We denote the category of all presheaves by $PreShv(\mathcal{C})$. Any object X of $\mathcal{C}$ defines a presheaf $R_X : Y \mapsto Hom_{\mathcal{C}}(Y, X)$ which is called the presheaf representable by X. By Yoneda Lemma the correspondence $X \mapsto R_X$ identifies $\mathcal{C}$ with the subcategory of representable presheaves on $\mathcal{C}$. The category $PreShv(\mathcal{C})$ has all small colimits (and limits). Moreover any presheaf is the colimit of a canonical diagram of representable presheaves. Thus $PreShv(\mathcal{C})$ is in a sense the category obtained from $\mathcal{C}$ by formal addition of all small colimits.

It is quite possible to develop homotopy theory for algebraic varieties taking the category $PreShv(Sm/S)$ as the category Spc of spaces. However this approach has a disadvantage which can be illustrated by the following example. For two subspaces A, B of a space X denote by $A \cup B$ the colimit of the diagram

$$
\begin{array}{ccc}
A \cap B & \to & A \\
\downarrow & & \\
B & &
\end{array}
\tag{1}
$$

where $A \cap B = A \times_X B$ is the fiber product of A and B over X. This is the categorical definition of union which makes sense in any category with limits and colimits. Consider now a covering $X = U \cup V$ of a scheme X by two Zariski open subsets U and V. The square

$$
\begin{array}{ccc}
U \cap V & \to & U \\
\downarrow & & \downarrow \\
V & \to & X
\end{array}
\tag{2}
$$

is a pushforward square in Sm/S and thus X is the categorical union of U and V

in Sm/S. However the corresponding square of representable presheaves

$$\begin{array}{ccc} R_{U\cap V} & \to & R_U \\ \downarrow & & \downarrow \\ R_V & \to & R_X \end{array} \qquad (3)$$

is *not* a pushforward square in $PreShv(Sm/S)$ unless $U = X$ or $V = X$. Thus if we define spaces as presheaves the union $U \cup_{PreShv} V$ of U and V as spaces is not the same as X. There is a morphism $j_{U,V} : U \cup_{PreShv} V \to X$ but it is not an isomorphism.

DEFINITION 2.1 *An elementary distinguished square in Sm/S is a square of the form*

$$\begin{array}{ccc} p^{-1}(U) & \to & V \\ \downarrow & & \downarrow p \\ U & \overset{j}{\to} & X \end{array} \qquad (4)$$

such that p is an etale morphism, j is an open embedding and $p^{-1}(X-U) \to X-U$ is an isomorphism (here $X - U$ is the maximal reduced subscheme with support in the closed subset $X - U$).

An important class of elementary distinguished squares is provided by coverings $X = U \cup V$ by two Zariski open subsets. In this case $p = j_V$ is an open embedding and the condition that $p^{-1}(X-U) \to X-U$ is an isomorphism is equivalent to the condition that $U \cup V = X$. One can easily see that an elementary distinguished square is a pushforward square in Sm/S i.e. X is the colimit of the diagram

$$\begin{array}{ccc} p^{-1}(U) & \to & V \\ \downarrow & & \\ U & & \end{array} \qquad (5)$$

We want to define our category of spaces in such a way that elementary distinguished squares remain pushforward squares when considered in this category of spaces. The technique which allows one to add new colimits taking into account already existing ones is the theory of sheaves on Grothendieck topologies.

DEFINITION 2.2 *A contravariant functor $F : Sm/S \to Sets$ (= a presheaf on Sm/S) is called a sheaf in Nisnevich topology if the following two conditions hold*

1. *$F(\emptyset) = pt$*

2. *for any elementary distinguished square as in Definition 2.1 the square of sets*

$$\begin{array}{ccc} F(X) & \to & F(V) \\ \downarrow & & \downarrow \\ F(U) & \to & F(p^{-1}(U)) \end{array} \qquad (6)$$

   is Cartesian i.e. $F(X) = F(U) \times_{F(p^{-1}(U))} F(V)$.

Denote the full subcategory of $PreShv(Sm/S)$ which consists of sheaves in Nisnevich topology by $Shv_{Nis}(Sm/S)$. This is our category of spaces. Because elementary distinguished squares are pushforward squares in Sm/S any representable presheaf belongs to $Shv_{Nis}(Sm/S)$. Thus the functor $X \mapsto R_X$ factors through an embedding $Sm/S \to Shv_{Nis}(Sm/S)$. We will use this embedding to identify smooth schemes with the corresponding spaces (= representable sheaves). By Yoneda Lemma and our definition the square of representable sheaves corresponding to an elementary distinguished square is a pushforward square in $Shv_{Nis}(Sm/S)$. The following result is a corollary of the general theory of sheaves on Grothendieck topologies.

THEOREM 2.3 *The category $Shv_{Nis}(Sm/S)$ has all small limits and colimits. The inclusion functor $Shv_{Nis}(Sm/S) \to PreShv(Sm/S)$ has a left adjoint a_{Nis} : $PreShv(Sm/S) \to Shv_{Nis}(Sm/S)$ which commutes with both limits and colimits.*

The functor a_{Nis} is called the functor of associated sheaf. To compute a colimit in $Shv_{Nis}(Sm/S)$ one first computes it in $PreShv(Sm/S)$ and then applies functor a_{Nis}. Starting from this point we denote the category $Shv_{Nis}(Sm/S)$ by Spc or $Spc(S)$ and its final object i.e. the space corresponding to the base scheme S by pt.

We will need a definition of a subcategory Spc^{ft} of spaces of finite type in Spc whose objects play the role of compact spaces in topology. We define Spc^{ft} as the smallest subcategory in Spc which satisfies the following two conditions

1. spaces corresponding to smooth schemes over S belong to Spc^{ft}

2. if in a pushforward square $\begin{array}{ccc} A & \xrightarrow{i} & X \\ \downarrow & & \downarrow \\ B & \to & Y \end{array}$ spaces A, X and B belong to Spc^{ft}

and i is a monomorphism then Y belongs to Spc^{ft}.

The following proposition shows that spaces of finite type are compact objects of Spc in the sense of the categorical definition of compactness.

PROPOSITION 2.4 *For any space of finite type X and any filtered system of spaces X_α the canonical map $colim_\alpha Hom(X, X_\alpha) \to Hom(X, colim_\alpha X_\alpha)$ is a bijection.*

A pointed space (X, x) is a space togther with a morphism $x : pt \to X$. We will also denote by x the subspace $x(pt) = Im\, x$ of X. For a space X and a subspace $A \subset X$ denote by X/A the "quotient space" i.e. the colimit of the diagram

$$\begin{array}{ccc} A & \to & X \\ \downarrow & & \\ pt & & \end{array} \qquad\qquad (7)$$

We always consider X/A as a pointed space with the distinguished point given by the canonical morphism $pt \to X/A$. For two pointed spaces (X, x), (Y, y) define their smash product as $(X, x) \wedge (Y, y) = X \times Y/(X \times y) \cup (x \times Y)$.

As an example of how all these definitions work consider Thom spaces of vector bundles. For a vector bundle $E \to U$ over a smooth scheme U over S set $Th(E) = E/(E - s(U))$ where $s : U \to E$ is the zero section. For two vector bundles $E \to X$ and $F \to Y$ we have

$$Th(E \times F) = E \times F/(E \times F - s(X \times Y)) = Th(E) \wedge Th(F)$$

Note that in order to have this equality we need to know that

$$E \times F - s(X \times Y) = ((E - s(X)) \times F) \cup (E \times (F - s(Y)))$$

i.e. that the square

$$
\begin{array}{ccc}
(E - s(X)) \times (F - s(Y)) & \to & (E - s(X)) \times F \\
\downarrow & & \downarrow \\
E \times (F - s(Y)) & \to & E \times F - s(X \times Y)
\end{array}
\tag{8}
$$

is a pushforward square. It is true in our case because this is the elementary distinguished square associated to a Zariski open covering.

3　Unstable homotopy category

To do homotopy theory in Spc we have to define classes of weak equivalences, fibrations and cofibrations. We start with the class of weak equivalences. We shall proceed in the same way as one does in homotopy theory of simplicial sets. We first define an analog of Kan simplicial sets and Kan completion functor. Then the analog of homotopy groups and then define weak equivalences as morphisms inducing isomorphisms on homotopy groups. Theorem 3.6 below shows that this definition is equivalent to another, more technical one, given in [14].

Denote by Δ_S^n the closed subscheme in $\mathbf{A}_S^{n+1}$ given by the equation $\sum_{i=0}^n x_i = 1$. Clearly Δ_S^n is a smooth scheme over S which is noncanonically isomorphic to $\mathbf{A}_S^n$. For any map of sets $\phi : \{0, \dots, n\} \to \{0, \dots, m\}$ define a morphism $\phi_S : \Delta_S^n \to \Delta_S^m$ setting $\phi_S^*(x_i) = \sum_{j \in \phi^{-1}(i)} x_j$. This gives us a functor from the standard simplicial category Δ to Sm/S and thus to Spc. Since Spc has all colimits this functor has the right Kan extension $|-|_S : \Delta^{op} Sets \to Spc$ which is characterized by the properties that it commutes with colimits and $|\Delta^n|_S = \Delta_S^n$.

Example 3.1 Let $\partial \Delta^2$ be the boundary of the standard 2-simplex i.e. the simplicial set whose geometrical realization looks like the boundary of an equilateral triangle. Then $|\partial \Delta^2|_S$ is the space which is a union of three affine lines in the form of a triangle with sides extended to infinity. Similarly $|\partial \Delta^3|_S$ is the union of four affine planes in the form of a tetrahedra.

For a space X and a smooth scheme U consider the sets $Sing_n(X)(U) = Hom(U \times \Delta_S^n, X)$. Since $\Delta_S^\bullet$ is a cosimplicial space these sets form a simplicial set $Sing_*(X)(U)$ which is a direct analog of the singular simplicial set of a topological space in the $\mathbf{A}^1$-theory.

DEFINITION 3.2 *A space X is called almost fibrant if for any open embedding $j : V \to U$ of smooth schemes over S the associated morphism of simplicial sets $Sing_*(X)(U) \to Sing_*(X)(V)$ is a Kan fibration.*

Note in particular that for any almost fibrant space X and any smooth scheme U the simplicial set $Sing_*(X)(U)$ is a Kan simplicial set.

Let $i_k^n : \Lambda_k^n \to \Delta^n$ be the inclusion of the "hat" simplicial set to the standard simplex and let $j : V \to U$ be an open embedding of smooth schemes over S. Consider the following embedding of spaces

$$i_{n,k,j} : U \times |\Lambda_k^n|_S \cup_{V \times |\Lambda_k^n|_S} V \times |\Delta^n|_S \to U \times |\Delta^n|_S$$

These embeddings for all n, k and $j : V \to U$ form the set of elementary "anodyne" morphisms which we can use to define our analog of Kan completion functor. For a space X let A_X be the set of all triples of the form $(\Lambda_k^n \to \Delta^n, j : V \to U, f : U \times |\Lambda_k^n|_S \cup_{V \times |\Lambda_k^n|_S} V \times |\Delta^n|_S \to X)$. We have a canonical diagram

$$\coprod_{A_X} U \times |\Lambda_k^n|_S \cup_{V \times |\Lambda_k^n|_S} V \times |\Delta^n|_S \quad \to \quad X$$
$$\downarrow \qquad\qquad\qquad\qquad\qquad\qquad (9)$$
$$\coprod_{A_X} U \times \Delta_S^n$$

and we define $Ex^1(X)$ as the colimit of this diagram. Clearly $Ex^1(X)$ is functorial in X and there is a canonical morphism $X \to Ex^1(X)$. Set $Ex^n(X) = Ex^1(Ex^{n-1}(X))$ and $Ex^\infty(X) = colim_n Ex^n(X)$. Proposition 2.4 immediately implies the following fact.

LEMMA 3.3 *The space $Ex^\infty(X)$ is almost fibrant for any space X.*

Let X be a space, U a smooth scheme and x an element in $Sing_0(X)(U) = Hom(U, X)$. Define homotopy "groups" $\pi_{i,U}^{\mathbf{A}^1}(X, x)$ as homotopy groups of the Kan simplicial set $C_*(Ex^\infty(X))(U)$ with respect to the base point x.

DEFINITION 3.4 *A morphism of spaces $f : X \to Y$ is called an $\mathbf{A}^1$-weak equivalence (or just weak equivalence) if for any smooth scheme U, any $x \in Hom(U, X)$ and any $i \geq 0$ the corresponding map of homotopy groups*

$$\pi_{i,U}^{\mathbf{A}^1}(X, x) \to \pi_{i,U}^{\mathbf{A}^1}(Y, f(x))$$

is a bijection.

DEFINITION 3.5 *The $\mathbf{A}^1$-homotopy category $H^{\mathbf{A}^1}(S)$ of smooth schemes over S is the localization of the category of spaces over S with respect to the class of weak equivalences.*

The following is the list of basic properties of weak equivalences. They can either be deduced from [14] using Theorem 3.6 or proven directly.

  1. the canonical morphism $\Delta_S^1 \to pt$ is a weak equivalence

2. if $f : X \to Y$ and $f' : X' \to Y'$ are weak equivalences then $f \times f' : X \times X' \to Y \times Y'$ is a weak equivalence

3. if in a pushforward square $\quad \begin{array}{ccc} X & \overset{f}{\to} & Y \\ g \downarrow & & \downarrow \ g' \end{array} \quad f$ is a weak equivalence and
$$\begin{array}{ccc} X' & \overset{f'}{\to} & Y' \end{array}$$
either f or g is a monomorphism then f' is a weak equivalence

4. let $(X_\alpha, f_{\alpha\beta} : X_\alpha \to X_\beta)$ be a filtered system of spaces such that the morphisms $f_{\alpha\beta}$ are weak equivalences. Then the morphisms $X_\gamma \to colim\, X_\alpha$ are weak equivalences.

Another approach to homotopy theory of spaces over S based on the use of homotopy theory of simplicial sheaves is developed in [14]. The following result shows that these two approaches are equivalent and therefore we can use the techical results of [14] in the context of definitions given above.

THEOREM 3.6 *A morphism of spaces is a weak equivalence in the sense of definition 3.4 if and only if its is an* $\mathbf{A}^1$*-weak equivalence in the sense of [14]. The category* $H^{\mathbf{A}^1}(S)$ *defined above is equivalent to the category* $\mathcal{H}^{\mathbf{A}^1}(S)$ *defined in [14].*

Let $\mathbf{W}$ be the class of weak equivalences. Define the class of cofibrations $\mathbf{C}$ in Spc as the class of all monomorphisms and the class of fibrations $\mathbf{F}$ as the class of morphisms having the rigtht lifting property with respect to morphisms from $\mathbf{C} \cap \mathbf{W}$ (see [8, p.26]). As a corollary of Theorem 3.6 we have.

THEOREM 3.7 *The classes* $(\mathbf{W}, \mathbf{F}, \mathbf{C})$ *form a proper closed model structure on* Spc.

Once we know the notions of weak equivalences, fibrations and cofibrations for spaces we can define them for pointed spaces. A morphism of pointed spaces is called a weak equivalence, fibration or cofibration if it is a weak equivalence, fibration or cofibration as a morphism of spaces with forgotten distinguished points. Standard reasoning shows that so defined classes form a proper closed model structure on the category $Spc_\bullet$ of pointed spaces. We denote the pointed homotopy category by $H_\bullet^{\mathbf{A}^1}(S)$. Properties 2 and 3 of weak equivalences from the list given above imply that the smash product gives a symmetric monoidal structure ([11, p.180]) on $H_\bullet^{\mathbf{A}^1}(S)$. The unit object of this monoidal structure is the space $(S \coprod S, i_S)$ which one denotes S^0 and calles 0-sphere.

The functor $|-|_S$ from simplicial sets to spaces takes weak equivalences of simplicial sets to weak equivalences of spaces and thus defines a functor from the ordinary homotopy category H^{top} to $H^{\mathbf{A}^1}$ (and from $H_\bullet^{top}$ to $H_\bullet^{\mathbf{A}^1}$). For any two simplicial sets X, Y one has a canonical morphism $|X \times Y|_S \to |X|_S \times |Y|_S$ which is not an isomorphism but always a weak equivalence. Therefore the functor from H^{top} to $H^{\mathbf{A}^1}$ commutes with products and the functor from $H_\bullet^{top}$ to $H_\bullet^{\mathbf{A}^1}$ commutes with smash products.

Define the *simplicial circle* S_s^1 as $|\Delta^1/\partial\Delta^1|_S$. Geometrically S_s^1 is the space obtained from the affine line $\mathbf{A}^1$ by identification of points 0 and 1. The smash product with S_s^1 is the *simplicial suspension functor*. We denote $(S_s^1)^{\wedge n}$ by S_s^n. This is the space obtained from $\mathbf{A}_S^n$ by contraction of the union of hyperplanes $x_i = 1, x_i = 0, i = 1,\ldots,n$ to the point. One can use the simplicial suspension to describe homotopy groups $\pi_{i,U}^{\mathbf{A}^1}(X,x)$ in terms of morphisms in the pointed homotopy category as follows.

LEMMA 3.8 *For any pointed space (X,x), smooth scheme U and $i \geq 0$ one has*

$$\pi_{i,U}^{\mathbf{A}^1}(X,x) = Hom_{H_\bullet^{\mathbf{A}^1}}(S_s^i \wedge U_+, (X,x))$$

where U_+ is the pointed space $(U \coprod S, i_S)$.

The notion of almost fibrant space turns out to be too restrictive in concrete applications. For example the Eilenberg-MacLane spaces used in Section 6.1 to build the Eilenberg-MacLane spectrum representing motivic cohomology are not almost fibrant. A wider class of quasi-fibrant spaces defined below turns out to be more useful.

DEFINITION 3.9 *A space X is called quasi-fibrant if for any smooth scheme U over S which is quasi-projective over an affine open subset in S the map of simplicial sets $Sing_*(X)(U) \to Sing_*(Ex^\infty(X))(U)$ is a weak equivalence.*

The role of quasi-fibrant spaces in the theory is partly explained by the following corollary of Lemma 3.8.

PROPOSITION 3.10 *Let (X,x) be a pointed quasi-fibrant space and U be a smooth scheme over S which is quasi-projective over an affine open subset in S. Then for any $i \geq 0$ one has $Hom_{H^{\mathbf{A}^1}}(S_s^i \wedge U_+, (X,x)) = \pi_i(Sing_*(X)(U),x)$.*

4 Spanier-Whitehead category

One of the fundamental differences between $H = H^{\mathbf{A}^1}$ and the ordinary homotopy category H^{top} lies in the fact that besides the simplicial circle S_s^1 there is another circle S_t^1 which we call Tate circle and which is defined as the space $\mathbf{A}^1 - \{0\}$ pointed by 1. The following lemma shows how different types of "spheres" can be expressed in $H_\bullet$ in terms of S_t^n and S_s^n.

LEMMA 4.1 *There are canonical isomorphisms in $H_\bullet$ of the form*

$$(\mathbf{A}^n - \{0\}, \mathbf{1}) \cong S_t^n \wedge S_s^{n-1}; \quad \mathbf{P}^n/\mathbf{P}^{n-1} \cong \mathbf{A}^n/\mathbf{A}^n - \{0\} \cong S_t^n \wedge S_s^n;$$

The Spanier-Whitehead category $SW = SW^{\mathbf{A}^1}(S)$ is the category obtained from $H_\bullet$ by stabilization with respect to the suspensions associated to the circles S_s^1 and S_t^1. For technical reasons it is more convenient to talk about stabilization with respect to one suspension associated with $S_s^1 \wedge S_t^1$ which leads to an equivalent category. Note that by Lemma 4.1 $S_t^1 \wedge S_s^1$ is canonically weakly equivalent to $\mathbf{A}^1/\mathbf{A}^1 - \{0\}$ and to $(\mathbf{P}^1, \infty)$.

The construction of SW from $H_\bullet$ is an example of a very simple general construction which allows one to "invert" an object in a symmetric monoidal category. Let $(\mathcal{C}, \wedge, \mathbf{1})$ be a symmetric monoidal category (here $\wedge$ denotes the monoidal structure and $\mathbf{1}$ is the unit object) and T an object in $\mathcal{C}$ ([11, p.157,180]). Denote by $\mathcal{C}[T^{-1}]$ the category whose objects are pairs of the form (X, n), $X \in ob(\mathcal{C})$, $n \in \mathbf{Z}$ and morphisms are given by

$$Hom((X, n), (X', n')) = colim_{m \geq -n, -n'} Hom_{\mathcal{C}}(T^{\wedge(m+n)} \wedge X, T^{\wedge(m+n')} \wedge X')$$

One can easily define composition of morphisms and check that $\mathcal{C}[T^{-1}]$ is indeed a category. The assigment $X \mapsto (X, 0)$ gives us a functor from $\mathcal{C}$ to $\mathcal{C}[T^{-1}]$.

DEFINITION 4.2 $SW = H_\bullet[(S_s^1 \wedge S_t^1)^{-1}]$.

The next step is to define a symmetric monoidal structure on $\mathcal{C}[T^{-1}]$ such that the canonical functor from $\mathcal{C}$ is a symmetric monoidal functor and the object $(T, 0)$ is invertible in $\mathcal{C}[T^{-1}]$. It turns out that there is an obvious obstruction to the existence of such a structure. Indeed, the group of automorphisms of an invertible object in a symmetric monoidal category is necessarily abelian. Thus the cyclic permutation on $T \wedge T \wedge T$ being in the commutatnt of Σ_3 must become identity in $Aut_{\mathcal{C}[T^{-1}]}((T, 0))$. If one tries to extend directly the monoidal structure from $\mathcal{C}$ to $\mathcal{C}[T^{-1}]$ one discovers that this condition is indeed necessary and sufficient for the obvious constructions to be well defined. Thus one gets the following general result.

THEOREM 4.3 *Let $(\mathcal{C}, \wedge, \mathbf{1})$ be a symmetric monoidal category and T an object such that the cyclic permutation on $T \wedge T \wedge T$ equals identity in $\mathcal{C}[T^{-1}]$. Then there exists a symmetric monoidal structure $\wedge$ on $\mathcal{C}[T^{-1}]$ such that $(X, n) \wedge (Y, m) = (X \wedge Y, n + m)$.*

The canonical functor $\mathcal{C} \to \mathcal{C}[T^{-1}]$ is then a symmetric monoidal functor and the object $T = (T, 0)$ is invertible with the canonical inverse given by $T^{-1} = (\mathbf{1}, -1)$.

LEMMA 4.4 *The cyclic permutation on $(S_s^1 \wedge S_t^1)^{\wedge 3}$ equals identity in $H_\bullet$.*

Combining Theorem 4.3 and Lemma 4.4 we get:

PROPOSITION 4.5 *The category SW has a structure of a symmetric monoidal category $(\wedge, S^0)$ such that the canonical functor $(H_\bullet, \wedge, S^0) \to (SW, \wedge, S^0)$ is symmetric monoidal and $((X, x), n) \wedge ((Y, y), m) = ((X, x) \wedge (Y, y), n + m)$.*

Denote the object (S^0, n) of SW by T^n and objects of the form $((X, x), 0)$ simply by (X, x). Then for any $n \in \mathbf{Z}$ one has a canonical isomorphism $((X, x), n) = T^n \wedge (X, x)$ which we will use to avoid notations of the form $((X, x), n)$ below.

PROPOSITION 4.6 *The category SW is an additive category.*

To get the abelian group structures on the Hom-sets in SW one observes that the image of S_s^2 in SW is an abelian cogroup object which is invertible with respect to the monoidal structure.

The last structure on SW which we want to describe is a structure of a *triangulated* category ([6, ch.IV]). To specify a triangulated structure on an additive category $\mathcal{D}$ one has to describe two things. One is an additive autoequivalence $S : \mathcal{D} \to \mathcal{D}$ which is called the shift functor and denoted by $X \mapsto X[1]$. Another one is a class of diagrams of the form $X \to Y \to Z \to X[1]$ called *distinguished triangles* (all such diagrams are called triangles). These data should satisfy some conditions listed for example in [6, p.239]. These conditions have the following fundamental corollary which makes triangulated structure into a surprisingly effective tool to produce long exact sequences and, more generally, spectral sequences.

LEMMA 4.7 *Let $X \to Y \to Z \to X[1]$ be a distinguished triangle in a triangulated category and U be any object of this category. Then the sequences of abelian groups*

$$\to Hom(U, X[n]) \to Hom(U, Y[n]) \to Hom(U, Z[n]) \to Hom(U, X[n+1]) \to$$

$$\to Hom(Z[n], U) \to Hom(Y[n], U) \to Hom(X[n], U) \to Hom(Z[n-1], U) \to$$

are exact.

All known long exact sequences can be traced back to this lemma applied to distinguished triangles in different triangulated categories. In our case we will construct the Mayer-Vietoris, Gysin and blow-up long exact sequences in homology and cohomology as the long exact sequences associated with distinguished triangles in the Spanier-Whitehead category SW (see Propositions 4.11-4.13).

Let us describe now the triangulated structure on SW. We define the shift functor by $X[1] = X \wedge S_s^1$. To define distinguished triangles we have to recall the notion of cofibration sequences in our context. Let $f : (X, x) \to (Y, y)$ be a morphism of pointed spaces. Define $cone(f)$ as the colimit of the diagram

$$
\begin{array}{ccl}
(X, x) & \overset{Id \wedge 1}{\longrightarrow} & (X, x) \wedge \Delta_S^1 \\
\downarrow & & \\
(Y, y) & &
\end{array}
\tag{10}
$$

where the vertical arrow is f and $\Delta_S^1 \cong \mathbf{A}_S^1$ is considered as a pointed space with the distinguished point 0. We have a canonical morphism $(Y, y) \to cone(f)$ which we denote η_f. For any commutative square

$$
\begin{array}{ccc}
(X, x) & \overset{f}{\to} & (Y, y) \\
\downarrow & & \downarrow \\
(X', x') & \overset{f'}{\to} & (Y', y')
\end{array}
\tag{11}
$$

we have a canonical morphism $cone(f) \to cone(f')$ which makes the diagram

$$
\begin{array}{ccc}
(Y, y) & \overset{\eta_f}{\to} & cone(f) \\
\downarrow & & \downarrow \\
(Y', y') & \overset{\eta_{f'}}{\to} & cone(f')
\end{array}
\tag{12}
$$

commutative. In particular for any f we have a canonical morphism $cone(f) \to cone((X, x) \to pt)$. The space on the right hand side is canonically isomorphic to $(X, x) \wedge S^1_s$ and therefore to any f we assigned in a canonical way a sequence

$$(X, x) \xrightarrow{f} (Y, y) \xrightarrow{\eta_f} cone(f) \xrightarrow{\epsilon_f} (X, x) \wedge S^1_s$$

which is called the *cofibration sequence* of f. The idea of the following definition is that the distinguished triangles in SW are exactly the triangles isomorphic to suspensions of images of cofibration sequences from $Spc_\bullet$.

DEFINITION 4.8 *A sequence of morphisms of the form* $A \to B \to C \to A[1]$ *in SW is called a distinguished triangle if there exist a morphism* $f : X \to Y$ *in $Spc_\bullet$, an integer n and isomorphisms*

$$\phi_1 : T^n \wedge X \to A; \quad \phi_2 : T^n \wedge Y \to B; \quad \phi_3 : T^n \wedge cone(f) \to C$$

in SW such that the following diagram commutes

$$
\begin{array}{ccccccc}
T^n \wedge X & \xrightarrow{Id \wedge f} & T^n \wedge Y & \xrightarrow{Id \wedge \eta_f} & T^n \wedge cone(f) & \xrightarrow{\alpha \circ (T^n \wedge \epsilon_f)} & (T^n \wedge X)[1] \\
\phi_1 \downarrow & & \phi_2 \downarrow & & \phi_3 \downarrow & & \phi_1[1] \downarrow \\
A & \to & B & \to & C & \to & A[1]
\end{array}
\tag{13}
$$

(here $\alpha = \alpha_{T^n, X}$ is the canonical isomorphism $T^n \wedge X[1] \to (T^n \wedge X)[1]$).

THEOREM 4.9 *The category SW with the shift functor and the class of distinguished triangles defined above is a triangulated category.*

The main application of Theorem 4.9 is that in combination with Lemma 4.7 it implies that any distinguished triangle in SW generates two long exact sequences of Hom-groups. To take advantage of this fact one has to have a way to produce interesting distinguished triangles. At the moment we know of three main types of such triangles which generate correspondingly Mayer-Vietoris, Gysin and blow-up long exact sequences. They are described in Propositions 4.11-4.13 below. In all three cases the proof is based on an unstable result from [14] combined with the following general lemma.

LEMMA 4.10 *Consider a commutative square in $Spc_\bullet$*

$$
\begin{array}{ccc}
(A, a) & \xrightarrow{i} & (X, x) \\
p \downarrow & & \downarrow p' \\
(Y, y) & \xrightarrow{i'} & (Z, z)
\end{array}
\tag{14}
$$

such that i is a monomorphism (= cofibration) and the canonical morphism $(X, x) \cup_{(A,a)} (Y, y) \to (Z, z)$ is a weak equivalence. Then there is a canonical morphism $(Z, z) \to (A, a) \wedge S^1_s$ in $H_\bullet$ such that the sequence

$$(A, a) \xrightarrow{p \oplus i} (Y, y) \oplus (X, x) \xrightarrow{i' \oplus p'} (Z, z) \to (A, a)[1]$$

is a distinguished triangle in SW.

In the propositions below we denote by X_+ the pointed space $(X \coprod pt, i_{pt})$ associated with a space X.

PROPOSITION 4.11 *For any elementary distinguished square as in Definition 2.1 there is a canonical distinguished triangle in SW of the form*

$$p^{-1}(U)_+ \to U_+ \oplus V_+ \to X_+ \to p^{-1}(U)_+[1]$$

In particular for the distinguished square associated to a Zariski open covering $X = U \cup V$ we get the Mayer-Vietoris distinguished triangle

$$(U \cap V)_+ \to U_+ \oplus V_+ \to X_+ \to (U \cap V)_+[1]$$

PROPOSITION 4.12 *Let $i : Z \to X$ be a closed embedding of smooth schemes over S and N the normal bundle to Z in X. Then there is a canonical Gysin distinguished triangle of the form $(X - Z)_+ \to X_+ \to Th(N) \to (X - Z)_+[1]$.*

PROPOSITION 4.13 *Let $i : Z \to X$ be a closed embedding of smooth schemes over S and $p : X_Z \to X$ the blow-up of Z in X. Then there is a canonical blow-up distinguished triangle of the form*

$$p^{-1}(Z)_+ \to Z_+ \oplus (X_Z)_+ \to X_+ \to p^{-1}(Z)_+[1]$$

The following Connectivity Theorem is the basis for the proof of convergence results for spectral sequences in the homotopy theory of algebraic varieties.

THEOREM 4.14 *Let (X, x) be a pointed smooth scheme over S, (Y, y) a pointed space and $m \in \mathbf{Z}$ an integer. Then one has*

$$Hom_{SW}((X, x), S_s^n \wedge S_t^m \wedge (Y, y)) = 0$$

for any $n > dim(X)$ where $dim(X)$ is the absolute dimension of X

Denote by SW^{ft} the full subcategory in SW which consists of objects isomorphic to objects of the form $T^n \wedge (X, x)$ for $(X, x) \in Spc^{ft}$. By definition of cofibration sequences and spaces of finite type this is a triangulated subcategory of SW. Lemma 4.10 implies that it coincides with the triangulated subcategory generated by objects of the form $T^n \wedge (X, x)$ for smooth schemes X over S. This category actually plays more important role in the theory than the category SW itself which is a wrong category to work with if we are interested in spaces not of finite type. The correct replacement for SW is the stable homotopy category $SH = SH^{\mathbf{A}^1}(S)$ discussed in the following section.

5 SPECTRA AND THE STABLE HOMOTOPY CATEGORY

The stabilization construction used to define the Spanier-Whitehead category in the previous section has a serious drawback. One of the good properties of the homotopy category $H = H_\bullet^{\mathbf{A}^1}(S)$ is the existence of infinite coproducts. For

any collection of pointed spaces (X_α, x_α) the space $\vee_\alpha (X_\alpha, x_\alpha)$ represents the coproduct of (X_α, x_α)'s in H i.e. for any (Y, y) one has

$$Hom_H(\vee_\alpha(X_\alpha, x_\alpha), (Y, y)) = \prod_\alpha Hom_H((X_\alpha, x_\alpha), (Y, y))$$

When we invert $S_s^1 \wedge S_t^1$ to get the Spanier-Whitehead category we lose this property. For a family of objects like $\{T^{-i}\}_{i \geq 0}$ there is clearly no coproduct (= direct sum) in SW. Moreover for an infinite family of pointed spaces (X_α, x_α) the space $\vee_\alpha (X_\alpha, x_\alpha)$ considered as an object of SW is not the coproduct of (X_α, x_α)'s in this category because infinite colimits do not commute with infinite products.

There is another way to stabilize H with respect to the suspension functor $(X, x) \mapsto T \wedge (X, x)$ associated to any pointed space T. The resulting category which we denote by $H[[T^{-1}]]$ is called the stable homotopy category of T-spectra or just the T-stable homotopy category. It has all coproducts and the canonical functor $\Sigma_T^\infty : H \to H[[T^{-1}]]$ takes $\vee_\alpha (X_\alpha, x_\alpha)$ to the direct sum of (X_α, x_α)'s in $H[[T^{-1}]]$. Unfortunately no one knows how to construct a category $H[[T^{-1}]]$ with properties described above from H. Instead we will have to build it directly from spaces.

Let T be a pointed space of finite type. A T-spectrum $\mathbf{E}$ is a sequence of pointed spaces E_i, $i \geq 0$ which are called terms of $\mathbf{E}$ and morphisms $e_i : T \wedge E_i \to E_{i+1}$ which are called the assembly morphisms of $\mathbf{E}$. A morphism of T-spectra $\mathbf{E} \to \mathbf{F}$ is a collection of morphisms of pointed spaces $E_i \to F_i$ which commute with the assembly morphisms. Denote the category of T-spectra by $Sp(Spc_\bullet, T)$. For a T-spectrum $\mathbf{E}$ define a family of functor $E^n : Spc_\bullet^{ft} \to Sets$, $n \in \mathbf{Z}$ setting

$$E^n(X, x) = colim_{i \geq max\{0, -n\}} Hom_H(T^{\wedge i} \wedge (X, x), T^{\wedge(i+n)} \wedge E_i)$$

where the maps in the inductive system are defined by the assembly morphisms of $\mathbf{E}$. A morphism of T-spectra $\mathbf{E} \to \mathbf{F}$ is called a stable weak equivalence if the corresponding natural transformations of functors $E^n(-) \to F^n(-)$ are isomorphisms for all $n \in \mathbf{Z}$.

Definition 5.1 *The category $H[[T^{-1}]]$ is the localization of $Sp(Spc_\bullet, T)$ with respect to the class of weak equivalences.*

The category of T-spectra has all small limits and colimits which are defined termwise. In particular for a collection of spectra $\mathbf{E}_\alpha = (E_{i,\alpha}, e_{i,\alpha})$ their coproduct in $Sp(Spc_\bullet, T)$ is given by $\oplus_\alpha \mathbf{E}_\alpha = (\vee_\alpha E_{i,\alpha}, (\delta_i \circ (\vee e_{i,\alpha})))$ where δ_i is the canonical isomorphism $T \wedge (\vee_\alpha E_{i,\alpha}) \to \vee_\alpha (T \wedge E_{i,\alpha})$. One can verify easily that it is also the direct sum in $H[[T^{-1}]]$ i.e. that for any spectrum $\mathbf{F}$ one has

$$Hom_{H[[T^{-1}]]}(\oplus_\alpha \mathbf{E}_\alpha, \mathbf{F}) = \prod_\alpha Hom_{H[[T^{-1}]]}(\mathbf{E}_\alpha, \mathbf{F})$$

For a pointed space (X, x) denote by $\Sigma_T^\infty (X, x)$ the T-spectrum $(T^{\wedge n} \wedge (X, x), Id)$. The functor Σ_T^∞ takes weak equivalences to stable weak equivalences and for any collection of spaces we have a canonical isomorphism

$\Sigma_T^\infty(\vee_\alpha(X_\alpha, x_\alpha)) \to \oplus_\alpha \Sigma_T^\infty(X_\alpha, x_\alpha)$. One can also verify easily that the functor $H \to H[[T^{-1}]]$ admits a canonical decomposition of the form $H \to H[T^{-1}] \to H[[T^{-1}]]$ where the second functor takes $((X, x), n)$ to the spectrum

$$\Sigma^\infty((X, x), n)_i = \begin{cases} pt & \text{for} \quad i < -n \\ T^{\wedge(i+n)} & \text{for} \quad i \geq -n \end{cases} \tag{15}$$

The following result is the main technical thing one needs to know to be able to use the construction described above.

THEOREM 5.2 *For any space of finite type* (X, x) *and any* T*-spectrum* **E** *one has*

$$Hom_{H[[T^{-1}]]}(\Sigma_T^\infty(X, x), \mathbf{E}) = colim_n\, Hom_H(T^{\wedge n} \wedge (X, x), E_n)$$

where the maps in the inductive system are defined by the assembly morphisms of **E**.

COROLLARY 5.3 *Let* (X, x), (Y, y) *be spaces of finite type. Then one has*

$$Hom_{H[[T^{-1}]]}(\Sigma_T^\infty(X, x), \Sigma_T^\infty(Y, y)) = \underset{n}{colim}\, Hom_H(T^{\wedge n} \wedge (X, x), T^{\wedge n} \wedge (Y, y))$$

For a T-spectrum **E** define **E**[1] to be the spectrum $(E_i \wedge S_s^1, e_i \wedge Id_{S_s^1})$. For a morphism of T-spectra $f : \mathbf{E} \to \mathbf{F}$ define the associated cofibration sequence

$$\mathbf{E} \to \mathbf{F} \to cone(f) \to \mathbf{E}[1]$$

in exactly the same way as we did for morphisms of pointed spaces in the previous section setting $\mathbf{E} \wedge \Delta_S^1$ to be the spectrum of the form $(E_i \wedge \Delta_S^1, e_i \wedge Id_{\Delta_S^1})$. A sequence of morphisms in $H[[T^{-1}]]$ is called a *distinguished triangle* if it is isomorphic to the image of the cofibration sequence for a morphism in $Sp(Spc_\bullet, T)$.

PROPOSITION 5.4 *For any pointed space* T *of finite type the category* $H[[(S_s^1 \wedge T')^{-1}]]$ *is additive and the shift functor and the class of distinguished triangles defined above satisfy the axioms of a triangulated structure.*

The following technical result allows one to apply the general representablility theorems proven in [16], [17], [18] to the stable homotopy category of algebraic varieties.

PROPOSITION 5.5 *For any space of finite type* T *and any Noetherian base scheme* S *the category* $H[[T^{-1}]]$ *is compactly generated and suspension spectra of spaces of finite type are compact. If in addition* S *can be covered by affine open subsets* $U_i = Spec(R_i)$ *such that* R_i *are countable rings then the subcategory of compact objects in* $H[[T^{-1}]]$ *is equivalent to a countable category.*

THEOREM 5.6 *Let* T *be a space of finite type such that the cyclic permutation on* $T^{\wedge 3}$ *equals identity in* $H[T^{-1}]$. *Then the category* $H[[T^{-1}]]$ *has a symmetric monoidal structure* $(\wedge, \mathbf{1})$ *such that:*

1. *for a spectrum* $\mathbf{E}$ *and a pointed space* (X, x) *the spectrum* $\mathbf{E} \wedge \Sigma_T^\infty (X, x)$ *is canonically isomorphic to* $(E_i \wedge (X, x), e_i \wedge Id_{(X,x)})$

2. *for a collection of spectra* $\mathbf{E}_\alpha$ *and a spectrum* $\mathbf{F}$ *there is a canonicall isomorphism*

$$(\oplus_\alpha \mathbf{E}_\alpha) \wedge \mathbf{F} \to \oplus_\alpha (\mathbf{E}_\alpha \wedge \mathbf{F})$$

3. *for a cofibration sequence* $\mathbf{E} \to \mathbf{F} \to cone(f) \overset{\epsilon}{\to} \mathbf{E}[1]$ *and a spectrum* $\mathbf{G}$ *the sequence* $\mathbf{E} \wedge \mathbf{G} \to \mathbf{F} \wedge \mathbf{G} \to cone(f) \wedge \mathbf{G} \to \mathbf{E} \wedge \mathbf{G}[1]$ *where the last morphism is the composition of* $\epsilon \wedge Id_G$ *with the canonical isomorphism* $\mathbf{E}[1] \wedge \mathbf{G} \to (\mathbf{E} \wedge \mathbf{G})[1]$ *is isomorphic to a cofibration sequence.*

All the results of this section except for Theorem 5.6 have simple proofs. I know of two ways to prove Theorem 5.6. One is to explicitly construct the symmetric monoidal structure on $H[[T^{-1}]]$ starting with the obvious badly defined smash product in $Sp(Spc_\bullet, T)$ and checking that all the ambiguities disappear when one passes to the homotopy category. In the case of the ordinary topological stable category a detailed exposition of this approach is given for example in [1, pp. 158-190]. It takes Adams thirty pages to verify that nothing goes wrong and it is terrible. Also it is hard to see that the cyclic permutation condition is indeed the key. Another way to prove Theorem 5.6 is to use the idea of symmetric spectra introduced recently by Jeff Smith (see [8] for an exposition in the context of simplicial sets and topological spaces). In this approach one defines first the category $Sp^\Sigma(Spc_\bullet, T)$ of so called symmetric T-spectra and the associated stable homotopy category which I denote $H[[T^{-1}, \Sigma]]$. These categories have symmetric monoidal structures for any T and one can construct a functor $H[[T^{-1}]] \to H[[T^{-1}, \Sigma]]$ which commutes in the obvious sense with the suspension spectrum functors. The cyclic permutation condition is then necessary and sufficient for this functor to be an equivalence [19].

This ends our discussion of the general stabilization construction $H \mapsto H[[T^{-1}]]$. Now we specialize to the only case which we are really interested in namely $T = S_s^1 \wedge S_t^1$. For the reasons which will become clear in the next section when we consider concrete examples of spectra we choose $(\mathbf{P}^1, \infty)$ as the model for $S_s^1 \wedge S_t^1$ used in the definition of SH.

DEFINITION 5.7 *The stable* $\mathbf{A}^1$*-homotopy category over* S *is the category*

$$SH(S) = H_\bullet^{\mathbf{A}^1}(S)[[(\mathbf{P}^1, \infty)^{-1}]]$$

We denote $SH(S)$ simply by SH and the suspension spectrum functor $\Sigma_{(\mathbf{P}^1, \infty)}^\infty$ by Σ^∞. The canonical functor $SW \to SH$ described on objects by (15) respects both the symmetric monoidal and the triangulated structures. In particular Propositions 4.11-4.13 have straightforward analogs in SH and in view of Theorem 5.2 the same is true for the Connectivity Theorem 4.14.

According to Theorem 5.6(1) and Lemma 4.1 for any $n \geq 0$ we have canonical isomorphisms

$$\Sigma^\infty(S_s^n) \wedge \Sigma^\infty(S_t^n, -n) \cong \mathbf{1}; \quad \Sigma^\infty(S_t^n) \wedge \Sigma^\infty(S_s^n, -n) \cong \mathbf{1}$$

and therefore we can define objects S_s^n and S_t^n of SH for all $n \in \mathbf{Z}$ as follows

$$S_s^n = \left\{ \begin{array}{lll} \Sigma^\infty(S_s^n) & \text{for} & n \geq 0 \\ \Sigma^\infty(S_t^n, -n) & \text{for} & n \leq 0 \end{array} \right. \quad S_t^n = \left\{ \begin{array}{lll} \Sigma^\infty(S_t^n) & \text{for} & n \geq 0 \\ \Sigma^\infty(S_s^n, -n) & \text{for} & n \leq 0 \end{array} \right. \quad (16)$$

6 Three cohomology theories

To any object $\mathbf{E}$ of SH we assign a *cohomology theory* $E^{p,q}(-)$ and a homology theory $E_{p,q}(-)$ on $Spc_\bullet$ given by

$$E^{p,q}(X, x) = Hom_{SH}(\Sigma^\infty(X, x), S_s^{p-q} \wedge S_t^q \wedge \mathbf{E})$$

$$E_{p,q}(X, x) = Hom_{SH}(S_s^{p-q} \wedge S_t^q, \mathbf{E} \wedge \Sigma^\infty(X, x))$$

The reason for this somewhat strange indexing is hidden in connections with the theory of motives. Propositions 4.11-4.13 together with Lemma 4.7 imply that any cohomology or homology theory constructed in this way has three types of long exact sequences called respectively Mayer-Vietoris, Gysin and blow-up exact sequences.

One can give a formal definition of a cohomology theory as a collection of functors $Spc_\bullet \to Ab$ satisfying some simple axioms and use Theorem 5.5 together with [16, Th. 3.1] to prove that any such theory is of the form $E^{p,q}$ for an object $\mathbf{E}$ of SH. Usefulness of this construction is restricted by the fact that in any formulation I know one has to start with a family of functors defined on the category of all spaces or, at least, on the subcategory of spaces of finite type and not just on the category of smooth schemes over S. On the other hand as the example of algebraic cobordism considered below shows the direct correspondence $\mathbf{E} \mapsto (E^{p,q}(-))_{p,q \in \mathbf{Z}}$ allows one to give simple definition for theories which would otherwise be hard to construct. The possibility to use the stable homotopy category to produce theories with desired properties is one of the key ingredients in the proof of the Milnor conjecture given in [26].

6.1 Motivic cohomology

Let us first define the *Eilenberg-MacLane spectrum* $\mathbf{H_Z}$ which represents a theory $H_{\mathbf{Z}}^{p,q}(-) = H^{p,q}(-, \mathbf{Z})$ called *motivic cohomology* (with integral coefficients). It is an analog of ordinary cohomology in the $\mathbf{A}^1$-homotopy theory. The theory of motivic cohomology described here was developed in [5] and [25] before the $\mathbf{A}^1$-homotopy theory was introduced. The first definition in terms of the stable homotopy category was given in [26]. The only technical result about motivic cohomology which we can not obtain as a specialization of general results in $\mathbf{A}^1$-homotopy theory is Theorem 6.2. If we knew how to prove this theorem without going through all the moves of [24] and [5] a major part of these papers would become obsolete at least as far as the theory of motivic cohomology is concerned. But we do not.

The tricky part in getting the $\mathbf{A}^1$-analog of the topological Eilenberg-MacLane spectrum is to guess what the Eilenberg-MacLane spaces in $Spc_\bullet$ are. The obvious

idea to take a space $K(\mathbf{Z}, n)$ which has the property that for any connected U

$$\pi_{i,U}(K(\mathbf{Z}, n)) = \begin{cases} 0 & \text{for} \quad i \neq n \\ \mathbf{Z} & \text{for} \quad i = n \end{cases} \tag{17}$$

does not work. To build a spectrum out of $K(\mathbf{Z}, n)$'s we would have to specify assembly morphisms $(\mathbf{P}^1, \infty) \wedge K(\mathbf{Z}, n) \to K(\mathbf{Z}, n+1)$ but a simple computation shows that any morphism of the form $(\mathbf{P}^1, \infty) \wedge (X, x) \to K(\mathbf{Z}, n+1)$ is trivial in the $\mathbf{A}^1$-homotopy category. The correct approach was discovered by A. Suslin around 1987. The idea is to define the $\mathbf{A}^1$-analogs of the Eilenberg-MacLane spaces through the Dold-Thom Theorem. For a pointed topological space $(T, *)$ let $Symm^\infty(T, *)$ be its infinite symmetric product $Symm^\infty(T, *) = colim_n Symm^n(T, *)$ where $Symm^n(T, *) = (T, *)^{\times n}/\Sigma_n$ and the maps $Symm^n \to Symm^{n+1}$ send $(x_1, \ldots, x_n)$ to $(x_1, \ldots, x_n, *)$. The Dold-Thom Theorem [4] says that for a connected pointed CW-complex $(T, *)$ the space $Symm^\infty(T, *)$ is weakly equivalent to the product $\prod_{i>0} K(H_i(T), i)$ where $H_i(T)$ are the integral homology of T. To formulate Dold-Thom Theorem for spaces which are not necessarily connected one considers $Symm^\infty(T, *)$ as a topological monoid with respect to the obvious addition and takes its group completion $(Symm^\infty(T, *))^+$. The general Dold-Thom theorem then says that

$$(Symm^\infty(T, *))^+ \cong \prod_{i \geq 0} K(H_i(T), i)$$

for any T and that in the case of a connected T the group completion does not change the homotopy type of $Symm^\infty(T, *)$. In particular one way to define $K(\mathbf{Z}, n)$ for all $n \geq 0$ is to set

$$K(\mathbf{Z}, n) = (Symm^\infty(S^n))^+$$

Once we understand the correct analog of the symmetric product construction in the $\mathbf{A}^1$-context this definition works perfectly well and gives us Eilenberg-MacLane spaces which fit together into the Eilenberg-MacLane spectrum representing motivic cohomology.

Assume for a moment that the base scheme S is regular. For a smooth scheme X over S and a smooth connected scheme U define $c(U, X)$ as the free abelian group generated by closed irreducible subsets Z of $U \times X$ which are finite and surjective over U. For any morphism $U_1 \to U_2$ over S one can define the base change homomorphism $c(U_2, X) \to c(U_1, X)$ which makes $c(-, X)$ into a contravariant functor from Sm/S to abelian groups. One can verify easily that this functor takes elementary distinguished squares to Cartesian squares i.e. that it is a *space* in the sense of our definition. We consider it as a pointed space with the distinguished point given by zero and denote by $L(X)$. If S is not regular the correct definition of $c(U, X)$ and $L(X)$ becomes more technical and requires the theory of realtive equidimensional cycles developed in [22]. In the notations of that paper $c(U, X) = c(U \times_S X/U, 0)$ ([22, p.30]). The graph of any morphism $U \to X$ is an element of $c(U, X)$ which gives us canonical maps $Hom(U, X) \to c(U, X)$ i.e. a morphism of spaces $X \to L(X)$.

It turns out that the space $L(X)$ plays the role of $(Symm^\infty(X_+))^+$ in our context. Intuitively one can see this as follows. Assume $S = Spec(k)$ and X is a smooth variety over k. Consider first the subspace $L^{eff}(X)$ in $L(X)$ which consists of formal linear combinations of closed subsets with nonnegative coefficients. A point in $L^{eff}(X)$ i.e. an element in $Hom_{Spc}(pt, L^{eff}(X)) = c^{eff}(Spec(k), X)$ is, by definition, a formal linear combination of closed points of X with nonnegative coefficients which is exatly what one would expect from points of the infinite symmetric product. The whole space $L(X)$ is clearly obtained from $L^{eff}(X)$ by the naive group completion with respect to the obvious abelian monoid structure on $L^{eff}(X)$. A detailed discussion of how $L(X)$ relates to usual symmetric products for quasi-projective varieties over a field k can be found in [21, §6] and especially in [21, Th. 6.8] where

$$z_0^{eff}(Z) = \begin{cases} L(Z) & \text{if} \quad char(k) = 0 \\ L(Z)[1/char(k)] & \text{if} \quad char(k) > 0 \end{cases} \tag{18}$$

To define Eilenberg-MacLane spaces we should apply this construction to our spheres $S_s^n \wedge S_t^m$. To do it we have to say what $L(X)$ is for a space which is not a smooth scheme. Instead of giving a general definition we only consider spaces of the form $X/(\cup_{i=1}^n Z_i)$ where X is a smooth scheme and Z_i's are smooth subschemes in X such that all the intersections of Z_i's are also smooth over S. We call such spaces scheme-like. This class includes in particular the spaces $S_s^n \wedge S_t^m$ for all $n, m \geq 0$ and it is closed under smash products. We set

$$L(X/(\cup_{i=1}^n Z_i)) = (L(X)/(\sum_{i=1}^n L(Z_i)))_{ab}$$

where the subscript ab indicates that we take the quotient in the category of abelian group spaces and then forget the abelian group structure. It can be shown that any morphism of scheme-like spaces $f : X \to Y$ induces homomorphism $L(f) : L(X) \to L(Y)$ and that for an $\mathbf{A}^1$-weak equivalence f the morphism $L(f)$ is also an $\mathbf{A}^1$-weak equivalence.

DEFINITION 6.1 $K(\mathbf{Z}(n), 2n) = L((\mathbf{P}^1, \infty)^{\wedge n})$

The notation $K(\mathbf{Z}(n), 2n)$ has the same origin as the indexing in the definition of $E^{p,q}$'s and as Theorem 6.3 below shows is consistent with this indexing. In view of Lemma 4.1 and previous discussion this definition reads

$$K(\mathbf{Z}(n), 2n) \cong (Symm^\infty((S_s^1 \wedge S_t^1)^{\wedge n}))^+$$

One can show that the "wrong" Eilenberg-MacLane space $K(\mathbf{Z}, n)$ specified by (17) is weakly equivalent to $L(S_s^n)$.

For any smooth schemes X, Y over S there is a billinear morphism $L(X) \times L(Y) \to L(X \times Y)$ defined by external product of relative cycles (see [22, p. 54]) which is natural in X and Y. This implies that for scheme-like spaces X, Y we have a canonical morphism $L(X) \wedge L(Y) \to L(X \wedge Y)$. In particular we have canonical morphisms

$$m_{m,n} : K(\mathbf{Z}(m), 2m) \wedge K(\mathbf{Z}(n), 2n) \to K(\mathbf{Z}(n+m), 2n+2m)$$

Composing $m_{1,n}$ with the morphism $i \wedge Id$ where i is the canonical morphism $(\mathbf{P}^1, \infty) \to L(\mathbf{P}^1, \infty)$ we get the *assembly morphisms* of the Eilenberg-MacLane spectrum $\mathbf{H}_{\mathbf{Z}}$

$$e_n : (\mathbf{P}^1, \infty) \wedge K(\mathbf{Z}(n), 2n) \to K(\mathbf{Z}(n+1), 2n+2)$$

The main thechnical result about the motivic cohomology spectrum is the following theorem. This is the only theorem in the paper for which we do not know a good proof.

THEOREM 6.2 *Let S be a smooth variety over a field k of characteristic zero. Then the spaces $K(\mathbf{Z}(n), 2n)$ are quasi-fibrant (Definition 3.9) and the morphisms*

$$\tilde{e}_n : K(\mathbf{Z}(n), 2n) \to \Omega^1_{(\mathbf{P}^1, \infty)} K(\mathbf{Z}(n+1), 2n+2)$$

adjoint to the assembly morphisms are $\mathbf{A}^1$-weak equivalences.

Conjecturally the statement of Theorem 6.2 should be true for any regular base scheme S. There is an example of a normal surface over $\mathbf{C}$ with an isolated nonrational singularity for which the second half of the theorem does not hold. The only reason the condition on the characteristic of the base field appears in the theorem is because the proof is based on techniques developed in [5] and in particular requires [5, Lemma 5.4] which in turn uses Hironaka's resolution of singularities. Theorem 6.3 has the following corollary.

THEOREM 6.3 *Let U be a smooth quasi-projective variety over a field of characteristic zero. Then for any $n, i \geq 0$ there is a canonical isomorphism*

$$H_{\mathbf{Z}}^{2n-i,n}(U_+) = \pi_i(Sing_*(K(\mathbf{Z}(n), 2n)(U), *))$$

The groups on the right hand side can be easily identified with the motivic cohomology groups defined in [5, Definition 9.2] where the notation $H^p(-, \mathbf{Z}(q))$ is used instead of $H_{\mathbf{Z}}^{p,q}(-)$. Together with [5, Th. 8.2, Th. 8.3(1)] and [25, Prop. 4.2.9] this gives the following comparison between our motivic cohomology and higher Chow groups introduced by S. Bloch in [2].

THEOREM 6.4 *Let U be a smooth quasi-projective variety over a field of characteristic zero. Then there are canonical isomorphisms*

$$H_{\mathbf{Z}}^{p,q}(U_+) = CH^q(U, 2q-p)$$

6.2 ALGEBRAIC K-THEORY

The next cohomology theory which we are going to discuss is *algebraic K-theory*. This theory is the best known one of the three theories considered here and it is also the least convenient one to define in terms of the stable homotopy category. The first definition of higher K-groups which works properly for all Noetherian schemes was given by B. Thomason in [23]. An $\mathbf{A}^1$-homotopy invariant version of algebraic K-theory which agrees with Thomason K-theory for regular schemes

was defined by C. Weibel in [27]. What follows gives a description of a spectrum **BGL** which represents a theory which after reindexing coincides on Sm/S with Weibel's homotopy K-theory. The construction given here is very ugly and I am sure that there exists a better way to do it.

Denote by $BGL(d)$ the infinite Grassmannian $BGL(d) = colim_{N \geq d} G(d, N)$ where $G(d, N)$ is the Grassmannian of linear subspaces of dimension d in the standard linear space of dimension N which we denote by $\mathcal{O}^N$. The maps $G(d, N) \to G(d, N + 1)$ take $L \subset \mathcal{O}^N$ to $L \oplus \{0\} \subset \mathcal{O}^N \oplus \mathcal{O}$. We have canonical monomorphisms $BGL(d) \to BGL(1 + d)$ which take $L \subset \mathcal{O}^N$ to $\mathcal{O} \oplus L \subset \mathcal{O} \oplus \mathcal{O}^N$ and we denote by BGL the colimit $colim_{d \geq 0} BGL(d)$. The spectrum representing algebraic K-theory is defined as follows

$$\mathbf{BGL} = (Ex^{\mathbf{A}^1}(BGL \times \mathbf{Z}), e : (\mathbf{P}^1, \infty) \wedge Ex^{\mathbf{A}^1}(BGL \times \mathbf{Z}) \to Ex^{\mathbf{A}^1}(BGL \times \mathbf{Z}))$$

where $BGL \times \mathbf{Z} = \coprod_{i \in \mathbf{Z}} BGL$ and $Ex^{\mathbf{A}^1}(BGL \times \mathbf{Z})$ is a fibrant replacement of $BGL \times \mathbf{Z}$ in the sense of the closed model structure of Theorem 3.7. The reason we have to take $Ex^{\mathbf{A}^1}(BGL \times \mathbf{Z})$ instead of $BGL \times \mathbf{Z}$ itself is that the only way I know to define the assembly morphism is to define first a morphism $\bar{e} : (\mathbf{P}^1, \infty) \wedge (BGL \times \mathbf{Z}) \to BGL \times \mathbf{Z}$ in the homotopy category and then say that any morphism in the homotopy category with values in a fibrant object can be lifted to the category of spaces. It is a little ugly but it works. To specify e we will use the following result proven in [14].

THEOREM 6.5 *For any smooth scheme X over S and any $i \geq 0$ there is a canonical map*

$$K_i(X) \to Hom_{H_\bullet}(S_s^i \wedge X_+, BGL \times \mathbf{Z})$$

which is a bijection if S is regular (the K-groups on the left are Thomason K-groups [23]).

For a pointed scheme (X, x) denote by $K_n(X, x)$ the subgroup of $K_n(X)$ which consists of elements vanishing on x. For a pair of pointed smooth schemes (X, x), (Y, y) denote by $K_i((X, x) \wedge (Y, y))$ the subgroup in $K_i(X \times Y)$ which consists of elements vanishing on $X \times \{y\} \subset X \times Y$ and on $\{x\} \times Y \subset X \times Y$. Note that this is always a direct summand in $K_i(X \times Y)$. Theorem 6.5 has the following corollary.

COROLLARY 6.6 *Let (X, x), (Y, y) be pointed smooth schemes over S. Then for any $i \geq 0$ there is a canonical map*

$$K_i((X, x) \wedge (Y, y)) \to Hom_{H_\bullet}(S_s^i \wedge (X, x) \wedge (Y, y), BGL \times \mathbf{Z})$$

which is a bijection if S is regular.

To define the assembly morphism of the spectrum **BGL** we want to use Corollary 6.6 to compute the set of morphisms $(\mathbf{P}^1, \infty) \wedge (BGL \times \mathbf{Z}) \to BGL \times \mathbf{Z}$ in the $\mathbf{A}^1$-homotopy category. Unfortunately BGL is not a smooth scheme but a colimit of filtered system of such schemes which makes us to use the following lemma.

LEMMA 6.7 *Let* $(X_n, i_n : (X_n, x_n) \to (X_{n+1}, x_{n+1}))$ *be an inductive system of pointed spaces such that all the morphisms* i_n *are monomorphisms and* (Y, y) *be a pointed space such that all the maps*

$$Hom_H(S_s^1 \wedge (X_{n+1}, x_{n+1}), (Y, y)) \to Hom_H(S_s^1 \wedge (X_n, x_n), (Y, y))$$

induced by $Id \wedge i_n$ *are surjective. Then the canonical map*

$$Hom_H(colim_n(X_n, x_n), (Y, y)) \to lim_n Hom_H((X_n, x_n), (Y, y))$$

is bijective.

Projective bundle theorem for algebraic K-theory together with standard geometrical constructions imply that the embeddings of Grassmannians $G(d, N) \to G(1 + d, 1 + N + 1)$ induce surjections of K-groups $K_n(G(1 + d, 1 + N + 1)) \to K_n(G(d, N))$ for all $n \in \mathbf{Z}$. The same projective bundle theorem appplied to the trivial bundle of dimension one implies that $K_n((\mathbf{P}^1, \infty) \wedge (X, x)) = K_n(X, x)$ for any pointed smooth scheme (X, x) over S. Thus Lemma 6.7 implies that for a regular scheme S one has

$$Hom_H((\mathbf{P}^1, \infty) \wedge (BGL \times \mathbf{Z}), BGL \times \mathbf{Z}) =$$

$$= lim_d Hom_H((\mathbf{P}^1, \infty) \wedge (\coprod_{i=-d}^{d} G(d, 2d)), BGL \times \mathbf{Z}) =$$

$$lim_d K_0((\mathbf{P}^1, \infty) \wedge (\coprod_{i=-d}^{d} G(d, 2d))) = \lim_d K_0(\coprod_{i=-d}^{d} G(d, 2d)) =$$

$$\lim_d Hom_H(\coprod_{i=-d}^{d} G(d, 2d), BGL \times \mathbf{Z}) = Hom_H(BGL \times \mathbf{Z}, BGL \times \mathbf{Z})$$

Denote by e the morphism $(\mathbf{P}^1, \infty) \wedge (BGL \times \mathbf{Z}) \to BGL \times \mathbf{Z}$ corresponding under these identifications to the identity morphism of $BGL \times \mathbf{Z}$ and define the assembly morphism of the spectrum $\mathbf{BGL}$ as a morphism of spaces which projects to e in the homotopy category. This defines $\mathbf{BGL}$ for regular base schemes S. To get $\mathbf{BGL}$ for any S one uses the inverse image functor on the homotopy categories associated with the canonical morphism $S \to Spec(\mathbf{Z})$. As an easy corollary of this construction of $\mathbf{BGL}$ we get the following *periodicity theorem*.

THEOREM 6.8 *There is a canonical isomorphism* $\mathbf{BGL} = S_s^1 \wedge S_t^1 \wedge \mathbf{BGL}$.

Thus from the point of view of the $\mathbf{A}^1$-theory algebraic K-theory is periodic with period $(2, 1)$ which is why it is usually written with only one index instead of two. While the construction of $\mathbf{BGL}$ presented here is not very nice it is actually easy to prove comparison theorems with it.

THEOREM 6.9 *For any Noetherian base scheme* S *and any smooth scheme* X *over* S *one has canonical isomorphisms*

$$BGL^{p,q}(X_+) = KH_{2q-p}(X)$$

where KH is the homotopy K-theory of [27]. In particular for a regular base S one has

$$BGL^{p,q}(X_+) = K_{2q-p}(X)$$

where K is the K-theory of [23].

6.3 ALGEBRAIC COBORDISM

Algebraic cobordism was introduced in [26] as one of the tools necessary for the proof of the Milnor conjecture. According to our current understanding it is the universal cohomology theory which has direct image homomorphisms for all smooth proper morphisms. It is represented by a spectrum $\mathbf{MGL} = (MGL(n), e_n)$ completely analogous to the Thom spectrum representing complex cobordism in the topological homotopy theory.

Recall that for a vector bundle E over X we defined its Thom space as $Th(E) = E/(E - s(X))$ where $s : X \to E$ is the zero section. For any morphism $f : X \to Y$ and a vector bundle E over Y we have a canonical morphism of spaces $Th(f^*E) \to Th(E)$. Let $E_{n,N}$ be the universal bundle over the Grassmannian $G(n, N)$. The embeddings $G(n, N) \to G(n, N + 1)$ induce morphisms $Th(E_{n,N}) \to Th(E_{n,N+1})$ and we define $MGL(n)$ as $colim_N Th(E_{n,N})$. To define assembly morphisms note that if $\mathcal{O}$ is the trivial bundle of dimension one then $Th(\mathcal{O} \oplus E) = (\mathbf{A}^1/\mathbf{A}^1 - \{0\}) \wedge Th(E)$. For the embeddings $f : G(n, N) \to G(1 + n, 1 + N)$ we have canonical isomorphisms $f^*(E_{1+n,1+N}) = \mathcal{O} \oplus E_{n,N}$ which implies that we have canonical morphisms $e'_n : (\mathbf{A}^1/\mathbf{A}^1 - \{0\}) \wedge MGL(n) \to MGL(n+1)$. Since the elementary distinguished square corresponding to the standard covering $\mathbf{P}^1 = \mathbf{A}^1 \cup \mathbf{A}^1$ is a pushforward square the morphism of quotient spaces $\mathbf{A}^1/(\mathbf{A}^1 - \{0\}) \to \mathbf{P}^1/(\mathbf{P}^1 - \{0\})$ is an isomorphism. The inverse gives us a morphism $\phi : (\mathbf{P}^1, \infty) \to \mathbf{A}^1/(\mathbf{A}^1 - \{0\})$. We define the *assembly morphisms* of the Thom spectrum $\mathbf{MGL}$ as compositions $e_n = e'_n \circ (\phi \wedge Id)$.

Since algebraic cobordism is a new theory we can not formulate here a comparison theorem as we have done with motivic cohomology and algebraic K-theory. Instead I will end this section with a conjecture which describes a part of algebraic cobordisms in terms of the usual complex cobordism ring MU^*.

CONJECTURE 1 *For any S there is a natural homomorphism $\oplus_{i=-\infty}^{\infty} MU^{2i} \to \oplus_{i=-\infty}^{\infty} MGL^{2i,i}(S)$ which is an isomorphism if S is local and regular.*

7 CONCLUDING REMARKS

This paper outlines the very basics of the $\mathbf{A}^1$-homotopy theory. One reason I did not say more about concrete computations such as the description of the motivic Steenrod algebra is that at the moment these computations can only be done in the case when S is a variety over a field of characteristic zero. This is partly due to the conditions of Theorem 6.2 and partly to technical difficulties in the proof of Spanier-Whitehead duality.

One of the two major directions of current work on the theory is to eliminate this restriction. There are two sources of new techniques which I believe will allow us to do it. One is related to the study of functoriality of the stable homotopy

categories with respect to S. There is a theory here which is largely parallel to the functoriality for the constructible sheaves in the etale topology [13, Ch.VI]. It allows in particular to prove the Spanier-Whitehead duality for smooth proper schemes over any base. However, just as in the etale theory there are certain statements which apparently require some kind of resolution of singularities (in the etale case this is for example the theorem saying that $\mathbf{R}p_*(\mathbf{Z}/n)$ is constructible for any morphism p of finite type [13, VI.5.7]). Surprisingly the same kind of problems comes up when one tries to generalize Theorem 6.2. I am rather optimistic about these problems at the moment. My optimism is mostly based on the amazing proof which Spencer Bloch gave for his localization theorem for higher Chow groups in [3]. It seems that he found a way to use Spivakovsky's solution of Hironaka's polyhedra game ([20]) instead of resolution of singularities to deal with problems essentially similar to the ones mentioned above.

The second main direction of current work can be described as an attempt to find an algebro-combinatorial description of $\mathbf{A}^1$-homotopy types. We do have a very hypothetical theory of *rational* homotopy type. The rational homotopy type of a scheme S is a differential graded Hopf algebra (commutative, not cocommutative) $\mathcal{H}_{\mathbf{Q}}(S)$ over $\mathbf{Q}$ such that the derived category of modules over $\mathcal{H}_{\mathbf{Q}}(S)$ is equivalent to the triangulated subcategory $DM^{lc}(S,\mathbf{Q})$ of local systems in the derived category $DM(S,\mathbf{Q})$ of modules over the Eilenberg-MacLane spectrum $\mathbf{H}_{\mathbf{Q}}$ over S.

In topological context $\mathcal{H}_{\mathbf{Q}}(T)$ is the differential graded Hopf algebra associated with the cosimplicial Hopf algebra $C^*(\Omega^1 T)$ of singular cochains on the first loop space of T and $DM^{lc}(T,\mathbf{Q})$ is the full subcategory of complexes with locally constant cohomology sheaves in the derived category of consructible sheaves of $\mathbf{Q}$-vector spaces on T.

In the particular case $S = Spec(k)$ the (weak) $K(\pi,1)$-conjecture says that $\mathcal{H}_{\mathbf{Q}}(S)$ is the Hopf algebra of functions on a proalgebraic group $Gal_{\mathcal{M},\mathbf{Q}}(k)$ (in particular it sits entirely in grading zero). This group is called the motivic Galois group of k. The category $DM^{lc}(S,\mathbf{Q})$ is in this case equivalent to the whole category $DM(S,\mathbf{Q})$ and the equivalence of the derived categories mentioned above becomes the known hypothetical correspondence between motives and representations of the motivic Galois group [15]. This wonderful picture whose origins go back to Grothendieck's idea of motives ([7], [12], [15]) must have an analog for integral homotopy types. All my attempts to find such an analog even in the case when S is the spectrum of an algebraically closed field of characteristic zero so far failed. We have a lot of knowledge about torison effects in the motivic category and this knowledge does not want to fit into any nice scheme.
